Minimax Multivariate Empirical Bayes Estimators under Multicollinearity

M.S. Srivastava* and T. Kubokawa†

University of Toronto and University of Tokyo

January 13, 2004

In this paper we consider the problem of estimating the matrix of regression coefficients in a multivariate linear regression model in which the design matrix is near singular. Under the assumption of normality, we propose empirical Bayes ridge regression estimators with three types of shrinkage functions, that is, scalar, componentwise and matricial shrinkage. These proposed estimators are proved to be uniformly better than the least squares estimator, that is, minimax in terms of risk under the Strawderman’s loss function. Through simulation and empirical studies, they are also shown to be useful in the multicollinearity cases.

Key words and phrases: Empirical Bayes estimator, ridge regression estimator, multicollinearity, multivariate linear regression model, multivariate normal distribution.

1 Introduction

Consider a multivariate linear regression model in which a vector \( y \) of \( p \) responses depends linearly on \( m \) independent variables \( z_1, \ldots, z_m \) as

\[
y = \beta' z + \epsilon
\]

where \( \epsilon \sim \mathcal{N}_p(0, \Sigma) \), \( z^t = (z_1, \ldots, z_m) \) and \( \beta \) is an \( m \times p \) matrix of unknown regression parameters. Writing

\[
\beta^t = (\beta_1, \ldots, \beta_m) \quad \text{and} \quad \beta = (\beta_{(1)}, \ldots, \beta_{(p)})
\]

we find that \( \beta_i \) is the vector of regression coefficients associated with the independent variables \( z_i \). With \( N \) independent observations on \( y \) and with the corresponding \( N \) values on \( z \) denoted by an \( N \times m \) matrix \( Z \) of rank \( m \), the regression model becomes

\[
Y = Z\beta + E,
\]
where

\[ Y = (y_{(1)}, \ldots, y_{(p)}) = (y_1, \ldots, y_N)^t : N \times p \]

and the \( N \) rows of \( E \) are i.i.d. \( \mathcal{N}_p(\mathbf{0}, \Sigma) \). The least squares estimate of \( \beta_{(i)} \) is given by

\[ \hat{\beta}_{(i)} = (Z^tZ)^{-1}Z^ty_{(i)}, \quad i = 1, \ldots, p \]

which can be written compactly as

\[ \hat{\beta} = (Z^tZ)^{-1}Z^tY. \]

When some of the independent variables \( z_1, \ldots, z_m \) are highly correlated, the matrix \( Z^tZ \) is near singular and the least squares estimator \( \hat{\beta} \) becomes unstable. In such a situation, known as multicollinearity in the literature, the regression coefficient vector \( \beta_i \) corresponding to the highly correlated independent variable \( z_i \) is shrunken or pulled towards zero by using Stein-type estimators or ridge-regression type estimators proposed by Hoerl and Kennard (1970). However, because of simplicity and ease of computation since the least squares computing packages can also be used for ridge regression estimators (see Sen and Srivastava, 1990, p 257), the ridge-regression estimator is a popular procedure among practicing statisticians. The most commonly used ridge regression estimator is given by

\[ (Z^tZ + K)^{-1}Z^tY, \]  

where \( K \) is an \( m \times m \) matrix chosen on the basis of some criteria; \( K \) is also sometimes chosen as a diagonal matrix. Some authors, such as Breiman and Friedman (1997), however, apply ridge regression estimators to \( \beta_{(i)} \) separately for each of the \( p \) regressions for the \( p \) response variables, namely, they consider

\[ \hat{\beta}_{(i)}(k_i) = (Z^tZ + k_iI)^{-1}Z^ty_{(i)}, \quad i = 1, \ldots, p. \]

While both (1.1) and (1.2) shrinks the matrix regression coefficients \( \beta \), it is not clear if either of them shrinks \( \hat{\beta}_i \) corresponding to the highly correlated variable \( z_i \).

In this paper we design the shrinkage in a manner that achieves the above mentioned goal of shrinking the ‘culprit’ \( \hat{\beta}_i \) towards zero. In addition, we provide minimax estimators under an appropriate loss function of the regression parameters. Attempts in the past to obtain minimax adaptive ridge regression estimators of the matrix \( K \) in (1.1) have not been successful, see for example, Brown and Zidek (1980, 82). On the other hand, minimax estimators of Stein-type (shrinkage) have been proposed in the literature for regression parameters by Bilodeau and Kariya (1989), Konno (1990, 1991) and Srivastava and Solanky (2003). However, Srivastava and Solanky (2003) have shown that one of the estimators proposed by Konno (1991) is the best among the many shrinkage estimators available in the literature including the one proposed by Breiman and Friedman (1997) whose minimaxity is not known. Thus in our comparison we shall include Konno’s estimator, defined in Section 4.

The organization of the paper is as follows: In Section 2, we reduce the problem to a canonical form and then propose empirical Bayes ridge regression estimators with three types of shrinkage functions, that is, scalar, componentwise and matricial shrinkage. In Section 3, these proposed estimators are proved to be uniformly better than the least
In Section 4, we investigate risk-behaviors of the proposed estimators, principal component regression estimators and Konno’s estimator under the loss function $L_j(\omega, \delta, (Z'Z)^j) = (\delta - \beta)^t(Z'Z)^j(\delta - \beta)$, $j = 0, 1, 2$. These procedures are also applied to the chemometrics data analyzed by Skagerberg, MacGregor and Kiparissides (1992) and compared through prediction error estimated via the leave-one-out cross-validation. Through these numerical and empirical studies, the minimax empirical Bayes ridge regression estimators are useful in the multicollinearity cases.

2 Minimax Empirical Bayes Ridge Regression Estimators

Following the notation of Srivastava and Khatri (1979, pp 54, 55), under the assumption of normality,

$$\tilde{\beta} \sim N_{m,p}(\beta, (Z'Z)^{-1}, \Sigma).$$

For obtaining minimax estimators of $\beta$, we shall consider the loss function

$$L(\omega, \tilde{\beta}, (Z'Z)^2) = \text{tr}(\tilde{\beta} - \beta)\Sigma^{-1}(\tilde{\beta} - \beta)^t(Z'Z)^2,$$

for any estimator $\tilde{\beta}$ of $\beta$ and $\omega = (\beta, \Sigma)$. This loss function was proposed by Strawderman (1978), and it is most appropriate for multicollinearity case.

Let $P$ be an $m \times m$ orthogonal matrix such that $P(Z'Z)^{-1}P^t = D = \text{diag}(d_1, \ldots, d_m)$ for $d_1 \geq \ldots \geq d_m > 0$. Then, with

$$X = P\tilde{\beta} \quad \text{and} \quad \Theta = P\beta,$$

we find that

$$X \sim N_{m,p}(\Theta, D, \Sigma).$$

In terms of the above transformations, the above loss function (2.1) becomes

$$L(\omega, \tilde{\Theta}, D^{-2}) = \text{tr}((\tilde{\Theta} - \Theta)\Sigma^{-1}(\tilde{\Theta} - \Theta)^tD^{-2},$$

(2.4)

where $\tilde{\Theta} = H\tilde{\beta}$ is an estimator of $\Theta$. Writing

$$X^t = (x_1, \ldots, x_m) \quad \text{and} \quad \Theta^t = (\theta_1, \ldots, \theta_m),$$

we find that $x_i$’s are independently distributed as

$$x_i \sim N_p(\theta_i, d_i\Sigma), \quad i = 1, \ldots, m.$$  

Here $d_i$’s are known numbers but $\Sigma$ is unknown which can be estimated by $n^{-1}S$ where

$$S = (Y - Z\tilde{\beta})^t(Y - Z\tilde{\beta}), \quad n = N - m,$$

and is distributed independently of $x_i$, $i = 1, \ldots, m$, as $W_p(n, \Sigma)$. Thus, the problem reduces to that of estimating $\theta_i$ from $x_i$ which has covariance $d_i\Sigma$, the inequality in covariances of $x_i$ is through the known numbers $d_i$.

Three types of empirical Bayes ridge regression estimators of $\Theta$ are proposed in the following subsections.
2.1 Scalar shrinkage empirical Bayes estimator

In the model $\mathbf{x}_i \sim \mathcal{N}_p(\theta_i, d_i \Sigma)$, $i = 1, \ldots, m$, where $d_1 \geq \ldots \geq d_m$, we suppose that $\theta_i$ has a prior distribution $\mathcal{N}_p(0, \lambda \Sigma)$. Then the posterior distribution of $\theta_i$ given $\mathbf{x}_i$ has $\mathcal{N}_p(\hat{\theta}_i^B(\lambda), (d_i^{-1} + \lambda^{-1})^{-1} \Sigma)$ where $\hat{\theta}_i^B(\lambda)$ is the Bayes estimator of $\theta_i$ given by

$$\hat{\theta}_i^B(\lambda) = \mathbf{x}_i - \frac{d_i}{d_i + \lambda} \mathbf{x}_i,$$

and the Bayes estimator of $\Theta$ is $\hat{\Theta}^B(\lambda)$ where $\{\hat{\Theta}^B(\lambda)\}^t = (\hat{\theta}_1^B(\lambda), \ldots, \hat{\theta}_m^B(\lambda))$. Since $\mathbf{x}_i$ is marginally distributed as $\mathcal{N}_p(0, (d_i + \lambda) \Sigma)$, we have that $E[\sum_{i=1}^{m} \mathbf{x}_i' \mathbf{S}^{-1} \mathbf{x}_i/(d_i + \lambda)] = mp/(n - p - 1)$. Taking this moment into account, we consider the solution $\lambda^*$ of the equation

$$\sum_{i=1}^{m} \mathbf{x}_i' \mathbf{S}^{-1} \mathbf{x}_i/(d_i + \lambda^*) = (mp - 2)/(n - p + 3).$$

Also let $\lambda_{s0}$ be the root of the equation

$$\sum_{i=1}^{m} \frac{d_i - d_m}{d_i + \lambda_{s0}} = \frac{pm - 2}{2p},$$

and define the estimator $\hat{\lambda}^{SB}$ of $\lambda$ by

$$\hat{\lambda}^{SB} = \max(\lambda^*, \lambda_{s0}).$$

We thus get the estimator $\hat{\Theta}^{SB} = (\hat{\theta}_1^{SB}, \ldots, \hat{\theta}_m^{SB})^t$ where

$$\hat{\theta}_i^{SB} = \hat{\theta}_i^B(\hat{\lambda}^{SB}) = \mathbf{x}_i - \frac{d_i}{d_i + \hat{\lambda}^{SB}} \mathbf{x}_i,$$

which we call the scalar shrinkage empirical Bayes estimator, denoted by SB.

**Theorem 1.** Assume that $pm \geq 3$. Then the scalar shrinkage empirical Bayes estimator $\hat{\Theta}^{SB}$ is minimax under Strawderman’s loss (2.4).

2.2 Componentwise shrinkage empirical Bayes estimator

Suppose that $\theta_i$ has a prior distribution $\mathcal{N}_p(0, \Sigma^{1/2} \Lambda \Sigma^{1/2})$ for $\Lambda = \text{diag}(\lambda_1, \ldots, \lambda_p)$. Then the posterior distribution of $\theta_i$ given $\mathbf{x}_i$ has $\mathcal{N}_p(\hat{\theta}_i^B(\Lambda, \Sigma), \Sigma^{1/2}(d_i^{-1} I_p + \Lambda^{-1})^{-1} \Sigma^{1/2})$ where $\hat{\theta}_i^B(\Lambda, \Sigma)$ is the Bayes estimator of $\theta_i$ given by

$$\hat{\theta}_i^B(\Lambda, \Sigma) = \left(d_i^{-1} \Sigma^{-1} + \Sigma^{-1/2} \Lambda^{-1} \Sigma^{-1/2}\right)^{-1} d_i^{-1} \Sigma^{-1} \mathbf{x}_i$$

$$= \mathbf{x}_i - d_i \Sigma^{1/2}(d_i I_p + \Lambda)^{-1} \Sigma^{-1/2} \mathbf{x}_i.$$ 

Since $\mathbf{x}_i$ is marginally distributed as $\mathcal{N}_p(0, \Sigma^{1/2}(d_i I_p + \Lambda) \Sigma^{1/2})$, the estimate of the parameter $\Lambda$ may be based on $\mathbf{S}$ and $\mathbf{X}$ by using their marginal distributions.
Let $H$ be an orthogonal matrix such that $HSH^t = L = \text{diag}(\ell_1, \ldots, \ell_p)$, $\ell_1 \geq \cdots \geq \ell_p$. For $j = 1, \ldots, p$, let $\lambda_j$ be the solution of the equation
\[
\sum_{i=1}^m \frac{(h_i^t x_i)^2/\ell_j}{d_i + \lambda_j} = c_0, \quad j = 1, \ldots, p,
\] (2.11)
where $H^t = (h_1, \ldots, h_p)$ and $c_0 = (m - 2)/(np + 2)$. Also let $\lambda_0$ be the solution of the equation
\[
\sum_{i=1}^m d_i - d_m = \frac{m - 2}{2},
\] (2.12)
and define the estimator $\hat{\lambda}_j^{CB}$ of $\lambda_j$ by
\[
\hat{\lambda}_j^{CB} = \max(\lambda_j^*, \lambda_0), \quad j = 1, \ldots, p.
\] (2.13)
We thus consider the estimator $\Theta^{CB} = (\hat{\theta}_1^{CB}, \ldots, \hat{\theta}_m^{CB})^t$ given by
\[
\hat{\theta}_i^{CB} = x_i - d_i H^t \Psi H x_i,
\] (2.14)
which we call the *componentwise shrinkage empirical Bayes estimator*, denoted by $CB$, where $\Psi = \text{diag}(\psi_1^{(i)}, \ldots, \psi_p^{(i)})$ for
\[
\psi_j^{(i)} = \frac{1}{d_i + \hat{\lambda}_j^{CB}}, \quad j = 1, \ldots, p.
\] (2.15)

**Theorem 2.** Assume that $m \geq 3$. Then the componentwise shrinkage empirical Bayes estimator $\Theta^{CB}$ is minimax under Strawderman’s loss (2.4).

We can also propose a convex combination of $\hat{\theta}_i^{SB}$ and $\hat{\theta}_i^{CB}$ as an estimator of $\theta_i$. For example,
\[
\hat{\theta}_i^{CC}(c) = \frac{c d_i}{c d_i + d_1} \hat{\theta}_i^{SB} + \frac{d_1}{c d_i + d_1} \hat{\theta}_i^{CB},
\] (2.16)
where $c$ is a constant, may be considered as a viable estimator. In the simulation and empirical studies given in Section 4, we put $c = 5$. This combined estimator of $\Theta$ is denoted by $\hat{\Theta}^{CC}(c)$. When $d_i$ is large, the combined estimator $\hat{\theta}_i^{CC}(c)$ is close to the scalar shrinkage empirical Bayes estimator $\hat{\theta}_i^{SB}$. When the $d_i$ is small, on the other hand, the componentwise shrinkage estimator $\hat{\theta}_i^{CB}$ will affect the risk gain effectively.

**Corollary 1.** The combined estimator $\hat{\Theta}^{CC}(c)$ is minimax if $m \geq 3$ under Strawderman’s loss.

### 2.3 Matricial shrinkage empirical Bayes estimator

Suppose that $\theta_i$ has a priori distribution $N_p(0, \Sigma^{1/2} \Gamma \Sigma^{1/2})$ for fully unknown positive definite matrix $\Gamma$. Then the posterior distribution of $\theta_i$ given $x_i$ has $N_p(\hat{\theta}_i^{B}(\Gamma, \Sigma), (d_i^{-1} \Sigma^{-1} + \Sigma^{-1/2} \Gamma^{-1} \Sigma^{-1/2})^{-1})$ where $\hat{\theta}_i^{B}(\Gamma, \Sigma)$ is the Bayes estimator of $\theta_i$ given by
\[
\hat{\theta}_i^{B}(\Gamma, \Sigma) = \left( d_i^{-1} \Sigma^{-1} + \Sigma^{-1/2} \Gamma^{-1} \Sigma^{-1/2} \right)^{-1} d_i^{-1} \Sigma^{-1} x_i
\]
\[
= x_i - d_i \Sigma^{1/2} (d_i I_p + \Gamma)^{-1} \Sigma^{1/2} x_i.
\] (2.17)
Since $x_i$ is marginally distributed as $\mathcal{N}_p(0, \Sigma^{1/2}(d_i I_p + \Gamma)\Sigma^{1/2})$, the estimate of the parameter $\Gamma$ may be based on $S$ and $X$ by using their marginal distributions. However, it seems difficult to provide the estimate as a solution of an equation like (2.6) and (2.11), so that we here treat another type of estimator. Let

$$A = \text{diag}(d_1 + 1, \ldots, d_m + 1)/(d_1 + 1),$$

(2.18)

and let $Q$ be a $(p \times p)$ nonsingular matrix such that

$$Q' SQ = I_p \quad \text{and} \quad Q' X' A^{-1} X Q = F,$$

(2.19)

where $F$ is a diagonal matrix, $F = \text{diag}(f_1, \ldots, f_p)$ and $f_1 \geq \cdots \geq f_p$. Clearly $f_i$'s are the eigenvalues of $S^{-1} X' A^{-1} X$. Let $\lambda_{m0}$ and $\lambda_{m1}$ be the solutions of the equations

$$\sum_{i=1}^m d_i - d_m = \frac{(p-1)(p+2)}{2p},$$

(2.20)

$$\sum_{i=1}^m d_i - d_m = \frac{m - p - 1}{2}.$$  

(2.21)

The adaptive ridge regression estimator of $\theta_i$ is given by

$$\hat{\theta}^{MB}_i = x_i - d_i (Q^t)^{-1} \Phi_i(F) Q' x_i, \quad i = 1, \ldots, m$$

(2.22)

where $\Phi_i(F) = \text{diag}(\phi_1^{(i)}, \ldots, \phi_p^{(i)})$ and for $j = 1, \ldots, p$,

$$\phi_j^{(i)} = \frac{1}{d_i + \lambda_{0}^{MB}} + \frac{1}{d_i + \lambda_{j}^{MB}},$$

(2.23)

$$\hat{\lambda}_{0}^{MB} = \max(c_0 \text{tr } F, \lambda_{m0}), \quad c_0 = \frac{n - p + 3}{(p-1)(p+2)},$$

(2.24)

$$\hat{\lambda}_{j}^{MB} = \max(c_1 f_j, \lambda_{m1}), \quad c_1 = \frac{n + p + 1}{m - p - 1}.$$  

(2.25)

It is noted that $\hat{\theta}^{MB}_i$ is close to the estimator proposed by Efron and Morris (1976) in the case of $d_1 = \cdots = d_m$. We can prove the minimaxity of the estimator $\hat{\Theta}^{MB}$ for $(\hat{\Theta}^{MB})' = (\hat{\theta}^{MB}_1, \ldots, \hat{\theta}^{MB}_m)$.

**Theorem 3.** Assume that $m \geq p + 2$. Then the estimator $\hat{\Theta}^{MB}$ is minimax under the loss (2.4).

We can also propose a convex combination of $\hat{\theta}^{SB}_i$ and $\hat{\theta}^{MB}_i$ as an estimator of $\theta_i$. One such estimator is given by

$$\hat{\theta}^{MC}_i(c) = \frac{cd_i}{cd_i + d_1} \hat{\theta}^{SB}_i + \frac{d_1}{cd_i + d_1} \hat{\theta}^{MB}_i,$$

(2.26)

where $c$ is a constant. In the simulation and empirical studies given in Section 4, we put $c = 5$.

**Corollary 2.** The combined estimator $\hat{\Theta}^{MC} (c)$ is minimax if $m \geq p + 2$ under Strawderman’s loss.
3 Proofs

In this section, we prove the three theorems stated in Section 2. It may be argued that since the first two cases are special cases of the matricial estimator, only the proof of Theorem 3 is required. However, different inequalities have been used in the proofs which lead to three different conditions in equations (2.7), (2.12) and (2.20) - (2.21) respectively. Thus, we need to provide proofs for all the three theorems. In the proofs, we need the following two well known results, one due to Stein (1973, 1981) and the other due to Stein-Ha (1977) and Ha (1979), known as the Stein-Ha identity.

**Lemma 1. (Stein Identity)** Let \( X = (X_1, \ldots, X_p)^t \) be a \( p \)-dimensional random variable having \( N_p(\theta, \Sigma) \). Consider a vector-valued absolutely continuous function \( h(X) = (h_1(X), \ldots, h_p(X))^t \) with \( E[|h(X) - \theta|^2] < \infty \). Then,
\[
E \left[ (X - \theta)\{h(X)\}^t \right] = E \left[ \Sigma \nabla \{h(X)\}^t \right],
\]
where \( \nabla = (\partial/\partial X_1, \ldots, \partial/\partial X_p)^t \).

**Lemma 2. (Stein-Ha Identity)** Let \( Y = (y_1, \ldots, y_n) \), where \( y_i \) are i.i.d. \( N_p(0, \Sigma) \) and \( V = YY^t = \sum_{j=1}^n Y_j Y_j^t \). Consider a \( p \times p \) matrix-valued function \( G(V) = (g_{ij}(V)) \), where \( g_{ij}(V) \) is a real-valued absolutely continuous function of the \( p \times p \) matrix \( V = (v_{ij}) \) and \( E[|g_{ij}(V)|] < \infty \). Then,
\[
E \left[ \text{tr} G(V) \Sigma^{-1} \right] = E \left[ (n - p - 1) \text{tr} G(V) V^{-1} + 2 \text{tr} D_G V \right],
\]
where \( (D_G V)_{ij} = \sum_k d_{ik} g_{kj}(V), \ d_{ik} = 2^{-1}(1 + \delta_{ik}) \partial/\partial v_{ik} \) and \( \delta_{ii} = 0 \) for \( i \neq k, \ \delta_{ii} = 1 \).

### 3.1 Proof of Theorem 1

In the proof below, we may assume without any loss of generality that \( \Sigma = I \). The risk difference between the two estimators is given by
\[
\Delta = R(\omega, \hat{\theta}^{SB}) - R(\omega, X)
= -2 \sum_{i=1}^m \frac{1}{d_i} E \left[ \frac{x_i^t (x_i - \theta_i)}{d_i + \lambda^{SB}} \right] + 2 \sum_{i=1}^m E \left[ \frac{x_i^t x_i}{(d_i + \lambda^{SB})^2} \right].
\]
from the Stein identity (3.1). Using the implicit function theorem, we get from (2.6)
\[
\sum_{i=1}^m \frac{x_i^t}{(d_i + \lambda^{SB})^2} \frac{\partial \lambda^{SB}}{\partial x_i} = -2 \sum_{i=1}^m \frac{x_i^t S^{-1} x_i (d_i + \lambda^{SB})^{-3}}{(d_i + \lambda^{SB})^{-2}} I(\lambda^* > \lambda_{m0}) < 2/(d_m + \lambda^{SB}).
\]
To evaluate the second term in (3.3), we use the Stein-Ha identity (3.2) giving
\[
E \left[ (d_i + \lambda^{SB})^{-2} \text{tr} x_i x_i^t \right]
= (n - p - 1) E \left[ (d_i + \lambda^{SB})^{-2} x_i x_i^t S^{-1} \right] + 2 E \left[ \text{tr} D_S [(d_i + \lambda^{SB})^{-2} x_i x_i^t] \right]
= (n - p - 1) E \left[ (d_i + \lambda^{SB})^{-2} x_i x_i^t S^{-1} \right] - 4 E \left[ (d_i + \lambda^{SB})^{-3} \sum_{j=1}^p \sum_{i=1}^p c_{ij} d_{jk}(\lambda^{SB}) \right].
\]
for \((c_{jk}^{(i)}) = x_i x_i^t\). From (2.6) and the implicit function theorem, we get
\[
d_{jk}(\lambda^*) = -\frac{\sum_{t=1}^{m}(d_t + \lambda^*)^{-1}(x_i^t f_j)(x_i^t f_k)}{\sum_{a=1}^{m}(d_a + \lambda^*)^{-2}x_i^t S^{-1}x_a},
\]
where \(S^{-1} = (f_1, \ldots, f_p)\), see Theorem 1.11.1 of Srivastava and Khatri (1979, p.28); the definition used in this paper requires to take half of the value given there. Thus,
\[
\sum_{j=1}^{p} \sum_{k=1}^{p} c_{jk}^{(i)} d_{jk}(\hat{\lambda}^*) = -\frac{\sum_{t=1}^{m}(d_t + \hat{\lambda}^*)^{-1}(x_i^t S^{-1}x_i)^2}{\sum_{a=1}^{m}(d_a + \hat{\lambda}^*)^{-2}x_i^t S^{-1}x_a}.
\]
From the Cauchy-Schwarz inequality \((x_i^t S^{-1}x_i)^2 \leq (x_i^t S^{-1}x_i)(x_i^t S^{-1}x_i)\), and hence
\[
\sum_{i=1}^{m} tr D_S(d_i + \hat{\lambda}^{SB})^{-1} x_i x_i^t
\]
\[
= 2 \sum_{i=1}^{m}(d_i + \hat{\lambda}^{SB})^{-3} \sum_{t=1}^{m}(d_t + \hat{\lambda}^{SB})^{-1}(x_i^t S^{-1}x_i)^2 I(\lambda^* > \lambda_0)
\]
\[
\leq 2(d_m + \hat{\lambda}^{SB})^{-1} \sum_{i=1}^{m}(d_i + \hat{\lambda}^{SB})^{-2}x_i^t S^{-1}x_i \sum_{t=1}^{m}(d_t + \hat{\lambda}^{SB})^{-1} x_i^t S^{-1}x_t
\]
\[
= 2(d_m + \hat{\lambda}^{SB})^{-1}(mp - 2)/(n - p + 3),
\]
from (2.6). Thus,
\[
\sum_{i=1}^{m} E \left[ (d_i + \hat{\lambda}^{SB})^{-2} x_i x_i^t \right]
\]
\[
\leq E \left[ (n - p - 1) \sum_{i=1}^{m}(d_i + \hat{\lambda}^{SB})^{-2} x_i^t S^{-1}x_i + 4(d_m + \hat{\lambda}^{SB})^{-1} \frac{mp - 2}{n - p + 3} \right]
\]
\[
\leq \frac{mp - 2}{n - p + 3} E \left[ (d_m + \hat{\lambda}^{SB})^{-1}(n - p - 1) + 4(d_m + \hat{\lambda}^{SB})^{-1} \right]
\]
\[
= (mp - 2) E \left[ (d_m + \hat{\lambda}^{SB})^{-1} \right]. \tag{3.5}
\]
Hence, combining (3.3), (3.4) and (3.5), we get
\[
\Delta \leq E \left[ -2p \sum_{i=1}^{m}(d_i + \hat{\lambda}^{SB})^{-1} + (mp + 2)(d_m + \hat{\lambda}^{SB})^{-1} \right].
\]
Thus, the risk difference is not positive if
\[
-2p \sum_{i=1}^{m}(d_i + \hat{\lambda}^{SB})^{-1} + (mp + 2)(d_m + \hat{\lambda}^{SB})^{-1} \leq 0. \tag{3.6}
\]
Noting that \(\sum_{i=1}^{m}(d_m + \hat{\lambda}^{SB})/(d_i + \hat{\lambda}^{SB}) = m - \sum_{i=1}^{m}(d_i - d_m)/(d_i + \hat{\lambda}^{SB})\), the inequality (3.6) is satisfied if
\[
\sum_{i=1}^{m}(d_i - d_m)/(d_i + \hat{\lambda}^{SB}) \leq (pm - 2)/(2p),
\]
which is guaranteed by the definition of \(\lambda_0\). Therefore Theorem 1 is proved. \(\blacksquare\)
3.2 Proof of Theorem 2

Let \( \mathbf{G} = (g_{ab}) = \mathbf{H} \Sigma^{1/2}, \mathbf{G}^{-1} = (g^{ab}), \mathbf{u}_i = (u_{i1}, \ldots, u_{ip})^t = d_i^{-1/2} \Sigma^{-1/2} \mathbf{x}_i \) and \( \eta_i = (\eta_{i1}, \ldots, \eta_{ip})^t = d_i^{-1/2} \Sigma^{-1/2} \mathbf{\theta}_i \). Then (2.11) can be rewritten as

\[
\sum_{k=1}^m \frac{d_k (\sum_b g_{ab} u_{bk})^2}{d_k + \lambda_a^*} = c_0 \ell_a, \quad a = 1, \ldots, p.
\]

From the implicit function theorem, we get

\[
\frac{\partial \lambda_a^*}{\partial u_{ji}} = 2 \frac{d_i (\sum_b g_{ab} u_{ba}) g_{aj} / (d_i + \lambda_a^*)}{\sum_k d_k (\sum_b g_{ab} u_{bk})^2 g_{aj} / (d_k + \lambda_a^*)^2},
\]

and from the definition of \( \psi_j^{(i)} = (d_i + \hat{\lambda}_j^{CB})^{-1} \) in (2.15),

\[
\frac{\partial \psi_a^{(i)}}{\partial u_{ji}} = -(d_i + \lambda_a^*)^{-2} (\partial \lambda_a^*/\partial u_{ji}) I(\lambda_a^* > \lambda_{c0}).
\]

The risk difference between the two estimators \( \hat{\Theta}^{CB} \) and \( \mathbf{X} \) is

\[
\Delta = -2 \sum_{i=1}^m E \left[ (\mathbf{u}_i - \eta_i)^t \mathbf{G}^{-1} \Psi_i \mathbf{G} \mathbf{u}_i \right] + \sum_{i=1}^m E \left[ \mathbf{x}_i^t \mathbf{H}^t \Psi_i \mathbf{H} \mathbf{x}_i \right]
\]

\[
= -2 \sum_{i=1}^m \sum_{j,a,b}^p E \left[ (u_{ji} - \eta_{ji}) g^{ja} \psi_a^{(i)} g_{ab} u_{ba} \right] + I_3
\]

\[
= -2 \sum_{i=1}^m \sum_{j,a,b}^p E \left[ \frac{\partial}{\partial u_{ji}} \{ g^{ja} \psi_a^{(i)} g_{ab} u_{ba} \} \right] + I_3
\]

\[
= -2 \sum_{i=1}^m \sum_{j,a,b}^p E \left[ g^{ja} \psi_a^{(i)} g_{ab} \delta_{bj} \right] - 2 \sum_{i=1}^m \sum_{j,a,b}^p E \left[ g^{ja} g_{ab} u_{ba} \frac{\partial \psi_a^{(i)}}{\partial u_{ji}} \right] + I_3
\]

\[
= -2 \sum_{i=1}^m \sum_{a=1}^p E \left[ \psi_a^{(i)} \right] + I_2 + I_3, \quad \text{(say)}
\]

using the Stein identity (3.1) and the fact that \( \sum_j g_{aj} g^{ja} = 1 \), where from (3.7) and (3.8)

\[
I_2 = 4 \sum_{j,a,b}^p E \left[ \frac{\sum_{i=1}^m g^{ja} g_{ab} u_{ba} d_i (d_i + \lambda_a^*)^{-3} g_{aj} (\sum_b g_{ab} u_{ba}) I(\lambda_a^* > \lambda_{c0})}{\sum_k d_k (\sum_b g_{ab} u_{bk})^2 / (d_k + \lambda_a^*)^2} \right]
\]

\[
= 4 \sum_{a=1}^p E \left[ \frac{\sum_{i=1}^m d_i (d_i + \lambda_a^*)^{-3} (\sum_b g_{ab} u_{ba})^2}{\sum_k d_k (\sum_b g_{ab} u_{bk})^2 / (d_k + \lambda_a^*)^2} I(\lambda_a^* > \lambda_{c0}) \right]
\]

\[
\leq 4 \sum_{a=1}^p E (d_m + \hat{\lambda}_a^{CB})^{-1}.
\]

Hence,

\[
\Delta \leq -2 \sum_{j=1}^p E \left[ \sum_{i=1}^m (d_i + \hat{\lambda}_j^{CB})^{-1} - 2(d_m + \hat{\lambda}_j^{CB})^{-1} \right] + I_3.
\]
From (2.11),
\[
\phi = \sum_{i=1}^{m} \sum_{j=1}^{p} (h'_{j}x_{i})^2 / [\ell_{j}(d_{i} + \hat{\lambda}_{j}^{CB})^2]
\]
\[
= \sum_{i=1}^{m} \text{tr} [\Psi_{i}Hx_{i}x'_{i}H_{i}\Psi_{i}L^{-1}] \leq c_{0} \sum_{j=1}^{p} (d_{m} + \hat{\lambda}_{j}^{CB})^{-1}.
\]

(3.12)

Let \( a_{jj} = (H'\Sigma^{-1}H)_{jj} \). Then, using the same arguments as in Sheena (1995), and the inequality \( \text{tr} (AB) \leq (\text{tr} A)(\text{tr} B) \) for \( A \) and \( B \) p.s.d. matrices, we get
\[
I_{3} \leq \sum_{i=1}^{m} E \left[ \{ \text{tr} H'\Psi_{i}Hx_{i}x'_{i}H_{i}\Psi_{i}H_{i}\Sigma^{-1} \} \{ \text{tr} S\Sigma^{-1} \} \right] = \sum_{j=1}^{p} E [a_{jj}\ell_{j}\phi]
\]
\[
= \sum_{j=1}^{p} E \left[ (n-p-1)\frac{\ell_{j}\phi}{\ell_{j}} + 2 \frac{\partial}{\partial \ell_{j}} (\ell_{j}\phi) + \sum_{c \neq j} \left( \frac{\ell_{j}\phi}{\ell_{j}} - \frac{\ell_{c}\phi}{\ell_{c}} \right) \right].
\]

(3.13)

From (2.11) and (3.12), we get
\[
2 \sum_{j=1}^{p} \ell_{j} \frac{\partial \phi}{\partial \ell_{j}} = -2 \sum_{j=1}^{p} \sum_{i=1}^{m} \left[ \frac{(h'_{j}x_{i})^2}{\ell_{j}(d_{i} + \hat{\lambda}_{j}^{CB})^2} - 2 \frac{(h'_{j}x_{i})^2}{(d_{i} + \hat{\lambda}_{j}^{CB})^3} \frac{\partial \hat{\lambda}_{j}^{CB}}{\partial \ell_{j}} \right]
\]
\[
= -2\phi + 4c_{0} \sum_{j=1}^{p} \sum_{i=1}^{m} \frac{(h'_{j}x_{i})^2}{(d_{i} + \lambda_{i}^{j})^3} I(\lambda_{i}^{j} > \lambda_{0})
\]
\[
\leq -2\phi + 4c_{0} \sum_{j=1}^{p} (d_{m} + \hat{\lambda}_{j}^{CB})^{-1}.
\]

(3.14)

Hence,
\[
I_{3} \leq (np + 2)c_{0} \sum_{j=1}^{p} E \left[ (d_{m} + \hat{\lambda}_{j}^{CB})^{-1} \right],
\]

and from (3.11),
\[
\Delta \leq \sum_{j=1}^{p} E \left[ -2 \sum_{i=1}^{m} (d_{i} + \hat{\lambda}_{j}^{CB})^{-1} + \{ 4 + (np + 2)c_{0} \} (d_{m} + \hat{\lambda}_{j}^{CB})^{-1} \right].
\]

(3.15)

Since
\[
\sum_{i=1}^{m} \frac{d_{m} + \hat{\lambda}_{j}^{CB}}{d_{i} + \hat{\lambda}_{j}^{CB}} \geq \sum_{i=1}^{m} \frac{d_{m} + \lambda_{i}^{0}}{d_{i} + \lambda_{i}^{0}} = m - \sum_{i=1}^{m} \frac{d_{i} - d_{m}}{d_{i} + \lambda_{i}^{0}},
\]
and \( c_{0} = (m-2)/(np + 2) \), the right hand side of (3.15) is less than zero if
\[
2 \sum_{i=1}^{m} \frac{d_{i} - d_{m}}{d_{i} + \lambda_{i}^{0}} - 2(m-2) + (m-2) \leq 0,
\]
which is guaranteed by (2.12). Therefore the proof of Theorem 2 is complete. 

\[
\Box
\]
3.3 Proof of Theorem 3

Let $G = \Sigma^{1/2}Q$, $a_i = (d_i + 1)/(d_i + 1)$, $\eta_i = \Sigma^{-1/2}\theta_i/\sqrt{a_i}$. Consider the transformations $u_i = \Sigma^{-1/2}x_i/\sqrt{a_i}$ and $V = \Sigma^{-1/2}S\Sigma^{-1/2}$. Then $u_i \sim N_p(\eta_i, (d_i/a_i)I)$ and $V \sim W_p(I, n)$. From (2.19), $V = (G^t)^{-1}G^{-1}$ and $U^tU = (G^t)^{-1}FG^{-1}$, where $U^t = (u_1, \ldots, u_m)$. Let $\Phi_* = \text{diag}(\phi_1^*, \ldots, \phi_p^*)$ for $\phi_j^* = (d_m + \lambda_0)^{-1} + (d_m + \lambda_j)^{-1}$ where $\lambda_0^{MB}$ and $\lambda_j^{MB}$ are here abbreviated $\lambda_0$ and $\lambda_j$, and $\Psi_* = \text{diag}(\psi_1^*, \ldots, \psi_p^*)$ for $\psi_j^* = f_j\phi_j^*$. Then it is seen that $\Phi_i \leq \Phi_*$ for $i = 1, \ldots, m$, since $d_m = \min_i(d_i)$.

To prove the theorem, we calculate the difference in the risks of the estimators $\Theta^{MB}$ and $X$ relative to the loss (2.4) is given by

$$\Delta = R(\omega, \Theta^{MB}) - R(\omega, X) = -2I_1 + I_2,$$

where, since $G^t = G^{-1}(GG^t) = G^{-1}V^{-1}$,

$$I_1 = \sum_{i=1}^m E\left[ a_i d_i^{-1}(u_i - \eta_i)^t(G^t)^{-1}\Phi_i G^{-1}V^{-1}u_i \right],$$

and, since $a_i \leq 1$ and $\Phi_i \leq \Phi_*$,

$$I_2 = \sum_{i=1}^m E\left[ a_i u_i^t G\Phi_i (G^t)^{-1}\Phi_i G^t u_i \right]$$

$$\leq E\left[ \text{tr} G\Phi_i (G^t)^{-1}\Phi_i G^t U^tU \right]$$

$$= E\left[ \text{tr} (G^t)^{-1}\Phi_i F\Phi_i G^{-1} \right] = E\left[ \text{tr} (G^t)^{-1}\Psi_i^2 F^{-1}G^{-1} \right]$$

$$= E\left[ (n - p - 1)\text{tr} \Psi_i^2 F^{-1}G^{-1} - 2\text{tr} D_V[(G^t)^{-1}\Psi_i^2 F^{-1}G^{-1}] \right]$$

$$= \sum_{j=1}^p E\left[ \frac{1}{f_j} \left\{ (n + p + 1)(\psi_j^*)^2 - 4f_j\psi_j^* \frac{\partial \psi_j^*}{\partial f_j} - 2f_j \sum_{a>j} (\psi_j^*)^2 - (\psi_i^*)^2 \right\} \right],$$

by using the Stein-Haff identity (3.2) and the following result due to Konno (1992):

$$\text{tr} D_V[(G^t)^{-1}\Phi(F)G^{-1}] = \sum_{j=1}^p \left\{ p\phi_j - f_j \frac{\partial \phi_j}{\partial f_j} - \sum_{c>j} f_j \phi_j - f_c \phi_c \right\}.$$

To evaluate $I_1$, we use some equations on the differential operator. Let $D_W = (d^W_{ij})$, where $d^W_{ij} = 2^{-1}(1 + \delta_{ij})\partial/\partial w_{ij}$ for $W = (w_{ij}) = U^tU$. Then Lo (1988) and Konno (1992) derived the following equations: For a $p \times p$ matricial function $T = T(W, V)$,

$$\nabla^T T = 2u_i^t D_W T \quad (3.19)$$

$$d^W_{ab} f_j = g_{aj}g_{bj} \quad (3.20)$$

$$d^W_{ab} g^{cd} = \frac{1}{2} \sum_{s \neq c} \frac{g^{sd}(g_{ac}g_{bs} + g_{bc}g_{as})}{f_c - f_s}, \quad (3.21)$$

where $G = (g_{ab})$, $G^{-1} = (g^{ab})$ and $\nabla^T_i = \partial/\partial u_i$. Now, we evaluate $I_1$ with the help of the
Stein identity (3.1). Using (3.19), we get

\[ I_1 = \sum_{i=1}^{m} E \left[ \nabla_i \left[ (G^t)^{-1} \Phi_i G^{-1} V^{-1} u_i \right] \right] \]
\[ = \sum_{i} E \left[ \left( \nabla_i \left[ (G^t)^{-1} \Phi_i G^{-1} V^{-1} \right] \right) u_i \right] + \sum_{i} E[\text{tr} \Phi_i] \]
\[ = 2 \sum_{i} E \left[ u_i^t D_W \left[ (G^t)^{-1} \Phi_i G^{-1} V^{-1} \right] u_i \right] + \sum_{i} E[\text{tr} \Phi_i] \]
\[ = I_{11} + I_{12}, \quad \text{(say)}. \] (3.22)

We evaluate \( I_{11} \) using (3.20) and (3.21) coordinatewise. Note that \( \sum_s g^{cb} g_{bj} = \delta_{cj} \), and

\[ (D_W [(G^t)^{-1} \Phi_i G^{-1}])_{a,d} = \sum_{b,c} (d^W_{ab} g^{cb}) \phi_c^{(i)} g^{cd} + \sum_{b,c} g^{cb} (d^W_{ab} \phi_c^{(i)}) g^{cd} + \sum_{b,c} g^{cb} \phi_c^{(i)} (d^W_{ab} g^{cd}). \] (3.23)

Since \( d^W_{ab} \phi_c^{(i)} = \sum_j (d^W_{ab} f_j) \partial \phi_c^{(i)}/\partial f_j = \sum_j g_{aj} g_{bj} \partial \phi_c^{(i)}/\partial f_j \), we observe that

\[ \sum_{b,c} g^{cb} (d^W_{ab} \phi_c^{(i)}) g^{cd} = \sum_{b,c,j} g^{cb} g_{aj} g_{bj} g^{cd} \partial \phi_c^{(i)}/\partial f_j \]
\[ = \sum_c g_{ac} (\partial \phi_c^{(i)}/\partial f_c) g^{cd}, \] (3.24)

Similarly, we obtain that

\[ \sum_{b,c} (d^W_{ab} g^{cb}) \phi_c^{(i)} g^{cd} = \frac{1}{2} \sum_{b,c} \phi_c^{(i)} g^{cd} \sum_{s \neq c} g^{sb} (g_{ac} g_{bs} + g_{bc} g_{as}) / (f_c - f_s) \]
\[ = -\frac{1}{2} \sum_c g_{ac} \left( \sum_{s \neq c} \phi_c^{(i)} / (f_c - f_s) \right) g^{cd} \] (3.25)

\[ \sum_{b,c} g^{cb} \phi_c^{(i)} (d^W_{ab} g^{cd}) = \frac{1}{2} \sum_s g_{as} \left( \sum_{c \neq s} \phi_c^{(i)} / (f_c - f_s) \right) g^{sd}. \] (3.26)

Combining (3.23), (3.24), (3.25) and (3.26) gives that

\[ (D_W [(G^t)^{-1} \Phi_i G^{-1}])_{a,b} = \sum_c g_{ac} \left\{ \frac{\partial \phi_c^{(i)}}{\partial f_c} + \frac{1}{2} \sum_{s \neq c} \frac{\phi_c^{(i)} - \phi_s^{(i)}}{f_c - f_s} \right\} g^{cb}, \]

which is written in the matricial form as

\[ D_W [(G^t)^{-1} \Phi_i G^{-1}] = G \Phi_i^{(1)} G^{-1} \] (3.27)

where \( \Phi_i^{(1)} = \text{diag} (\phi_{1,i}^{(1)}, \ldots, \phi_{p,i}^{(1)}) \) for

\[ \phi_{j,i}^{(1)} = \frac{\partial \phi_{j,i}^{(i)}}{\partial f_j} + \frac{1}{2} \sum_{a \neq j} \frac{\phi_{j,i}^{(i)} - \phi_{a,i}^{(i)}}{f_j - f_a}. \]
Note that the partial derivative of $\phi_j^{(i)}$, given by (2.23), is evaluated by

$$\frac{\partial\phi_j^{(i)}}{\partial f_j} = -\frac{c_0}{(d_i + \lambda_0)^2} I(c_0 \text{tr } F > \lambda_{m0}) - \frac{c_1}{(d_i + \lambda_j)^2} I(c_1 f_j > \lambda_{m1})$$

$$\geq -\frac{c_0}{(d_m + \lambda_0)^2} I(c_0 \text{tr } F > \lambda_{m0}) - \frac{c_1}{(d_m + \lambda_j)^2} I(c_1 f_j > \lambda_{m1}) = \frac{\partial\phi_j^{*}}{\partial f_j}.$$

(3.28)

Since $(\hat{\lambda}_j - \hat{\lambda}_a)/(f_j - f_a) \geq 0$, we get the inequality

$$\frac{\phi_j^{(i)} - \phi_a^{(i)}}{f_j - f_a} = -\frac{(\hat{\lambda}_j - \hat{\lambda}_a)/(f_j - f_a)}{(d_i + \lambda_j)(d_i + \lambda_a)}$$

$$\geq -\frac{(\hat{\lambda}_j - \hat{\lambda}_a)/(f_j - f_a)}{(d_m + \lambda_j)(d_m + \lambda_a)} = \frac{\phi_j^{*} - \phi_a^{*}}{f_j - f_a}.$$

(3.29)

Let $\Phi_{s}^{(1)} = \text{diag} \left( \phi_1^{(1)}, \ldots, \phi_p^{(1)} \right)$ for $\phi_j^{(1)} = \partial\phi_j^{*}/\partial f_j + 2^{-1} \sum_{a \neq j} (\phi_j^{*} - \phi_a^{*})/(f_j - f_a)$. Then from the inequalities (3.28) and (3.29), we observe that

$$I_{11} = 2 \sum_i E[u_i^{*} G \Phi_{s}^{(1)} G^{-1} V^{-1} u_i] = 2 \sum_i E[u_i^{*} G \Phi_{s}^{(1)} G^{t} u_i]$$

$$\geq 2 \sum_i E[u_i^{*} G \Phi_{s}^{(1)} G^{t} u_i] = 2 E[\text{tr } G \Phi_{s}^{(1)} G^{t} U^{t} U] = 2 E[\text{tr } \Phi_{s}^{(1)} F],$$

which, from (3.22), implies that

$$I_1 \geq \sum_{j=1}^{p} E \left[ \frac{1}{f_j} \left( \sum_i \psi_{j}^{(i)} + 2f_j \frac{\partial\phi_j^{*}}{\partial f_j} - 2\psi_j^{*} + f_j^2 \sum_{a \neq j} \frac{\psi_j^{*} - \psi_a^{*}}{f_j - f_a} \right) \right].$$

(3.30)

It is here noted that

$$\sum_{j} f_j \sum_{a \neq j} \frac{\psi_j^{*} - \psi_a^{*}}{f_j - f_a} = -(p-1) \sum_{j} \frac{\psi_j^{*}}{f_j} + \sum_{j} \sum_{a \neq j} \frac{\psi_j^{*} - \psi_a^{*}}{f_j - f_a}.$$

Then, combining (3.16), (3.17) and (3.30) gives that

$$\Delta \leq \sum_{j=1}^{p} E \left[ \frac{1}{f_j} \left( (n + p + 1)(\psi_j)^2 - 4f_j \psi_j^{*} \frac{\partial\psi_j^{*}}{\partial f_j} - 2f_j \sum_{a \neq j} (\psi_j^{*})^2 - (\psi_a^{*})^2 \right) \right]$$

$$- 2 \sum_{i=1}^{m} \psi_{j}^{(i)} + 2(p+1) \psi_j^{*} - 4f_j \frac{\partial\psi_j^{*}}{\partial f_j} - 4f_j \sum_{a \neq j} \frac{\psi_j^{*} - \psi_a^{*}}{f_j - f_a} \right) \right]\right]$$

$$\leq \sum_{j=1}^{p} E \left[ \frac{1}{f_j} \left( (n + p + 1)(\psi_j)^2 - 2 \sum_{i=1}^{m} \psi_{j}^{(i)} + 2(p+1) \psi_j^{*} \right) \right]$$

$$- 4f_j \frac{\partial\psi_j^{*}}{\partial f_j} - 2f_j \sum_{a \neq j} \frac{\psi_j^{*} - \psi_a^{*}}{f_j - f_a} (\psi_j^{*} + \psi_a^{*} + 2) \right) \right],$$

(3.31)

since $\partial\psi_j^{*}/\partial f_j \geq 0$. Noting that $\psi_j^{*} - \psi_a^{*} \geq (f_j - f_a)/(d_m + \hat{\lambda}_0)$ for $a > j$, we observe that

$$\sum_{j=1}^{p} \sum_{a \neq j} \frac{\psi_j^{*} - \psi_a^{*}}{f_j - f_a} (\psi_j^{*} + \psi_a^{*} + 2) \geq \frac{1}{d_m + \hat{\lambda}_0} \sum_{j=1}^{p} (\psi_j^{*} + \psi_a^{*} + 2)$$

$$= \frac{1}{d_m + \hat{\lambda}_0} \left( (p-1) \sum_{j=1}^{p} \psi_j^{*} + (p-1)p \right) \geq \frac{(p-1) \text{tr } F}{(d_m + \hat{\lambda}_0)^2} + \frac{(p-1)p}{d_m + \hat{\lambda}_0},$$

(3.32)
where we used the equations \( \sum_j \sum_{a>j} \psi_j^s = \sum_j (p-j)\psi_j^s \), \( \sum_j \sum_{a>j} \psi_j^s = \sum_j (j-1)\psi_j^s \) and \( \sum_j \sum_{a>j} 1 = (p-1)p/2 \). Also note that the partial derivative of \( \psi_j^s \) can be evaluated as

\[
\sum_{j=1}^p \frac{\partial \psi_j^s}{\partial f_j} = \sum_{j=1}^p \left\{ \frac{1}{d_m + \lambda_0} - \frac{c_0f_j}{(d_m + \lambda_0)^2} I(c_0 \text{tr } F > \lambda_{m0}) \right\} \geq \frac{p}{d_m + \lambda_0} - \frac{c_0 \text{tr } F}{(d_m + \lambda_0)^2} \geq \frac{p - 1}{d_m + \lambda_0}.
\]

(3.33)
since \( c_0 \text{tr } F \leq \lambda_0 \leq d_m + \lambda_0 \). Using the inequalities (3.32) and (3.33), the r.h.s. in (3.31) can be further evaluated as

\[
\Delta \leq E \left[ \sum_j \frac{1}{f_j} \left\{ (n+p+1)(\psi_j^s)^2 - 2 \sum_{i=1}^m \psi_j^{(i)} + 2(p+1)\psi_j^s \right\} - 2 \left( \frac{p-1}{d_m + \lambda_0} \right)^2 - 2 \left( \frac{p-1}{d_m + \lambda_0} \right) \right] = E[\Delta^*], \quad \text{(say)}.
\]

(3.34)

Finally, we shall show that \( \Delta^* \) is not positive. Noting that

\[
\sum_j \frac{(\psi_j^s)^2}{f_j} = \frac{\text{tr } F}{(d_m + \lambda_0)^2} + \frac{2}{d_m + \lambda_0} \sum_j \frac{f_j}{d_m + \lambda_j} + \sum_j \frac{f_j}{(d_m + \lambda_j)^2},
\]

we see that \( \Delta^* \) can be rewritten as \( \Delta^* = \Delta_1^* + \Delta_2^* \) where

\[
\Delta_1^* = \sum_j \frac{1}{d_m + \lambda_j} \left\{ \frac{(n+p+1)f_j}{d_m + \lambda_j} - 2 \sum_{i=1}^m \frac{d_m + \hat{\lambda}_j}{d_i + \lambda_j} + 2(p+1) \right\},
\]

\[
\Delta_2^* = (n+p+3)\frac{\text{tr } F}{(d_m + \lambda_0)^2} + \frac{2n+p+1}{d_m + \lambda_0} \sum_j \frac{f_j}{d_m + \lambda_j} - 2 \sum_{i=1}^m \frac{p}{d_i + \lambda_0}
\]

+ \frac{2p(p+1)}{d_m + \lambda_0} - \frac{2(p-1)(p+2)}{d_m + \lambda_0}.
\]

For \( \Delta_1^* \), it is noted that \( (n+p+1)f_j/(d_m + \hat{\lambda}_j) \leq (n+p+1)/c_1 = m-p-1 \), and that \( \sum_{i=1}^m (d_m + \hat{\lambda}_j)/(d_i + \lambda_j) \geq \sum_{i=1}^m (d_m + \lambda_{m1})/(d_i + \lambda_{m1}) \) since \( \lambda_j \geq \lambda_{m1} \). Hence, the inequality that \( \Delta_2^* \leq 0 \) is established if \( \lambda_{m1} \) satisfies the inequality

\[ m - p - 1 - 2 \sum_{i=1}^m (d_m + \lambda_{m1})/(d_i + \lambda_{m1}) + 2(p+1) \leq 0 \]

or

\[ \sum_{i=1}^m (d_i - d_m)/(d_i + \lambda_{m1}) \leq (m-p-1)/2, \]

which is guaranteed by (2.21). For \( \Delta_2^* \), the same arguments are used to show that

\[
(d_m + \hat{\lambda}_0)\Delta_2^* \leq \frac{n-p+3}{c_0} + \frac{2(n+p+1)p}{c_1} - 2p \sum_{i=1}^m \frac{d_m + \hat{\lambda}_0}{d_i + \lambda_0} + 2p(p+1) - 2(p-1)(p+2)
\]

\[ \leq - (p-1)(p+2) + 2mp - 2p \sum_{i=1}^m \frac{d_m + \hat{\lambda}_0}{d_i + \lambda_0}. \]
we want to investigate are the least squares estimator $X$ and $\Theta$.

Now we investigate the risk-performances of estimators of $\Theta$ numerically. The estimators we want to investigate are the least squares estimator $X$ and the proposed estimators $\tilde{\Theta}^{SB}$, $\tilde{\Theta}^{CB}$, $\tilde{\Theta}^{CC}$, $\tilde{\Theta}^{MB}$ and $\tilde{\Theta}^{MC}$, which are denoted by $LS$, $SB$, $CB$, $CC$, $MB$ and $MC$, respectively, where we put $c = 5$ for the constant $c$ in the estimators $\tilde{\Theta}^{CC}$ and $\tilde{\Theta}^{MC}$. The principal component regression estimators $PC_1$ and $PC_3$ are also treated where $PC_1$ is obtained by deleting the eigenvectors corresponding to the largest eigenvalue of $(Z'Z)^{-1}$ and $PC_3$ corresponds to the one obtained by deleting the three largest eigenvalues.

Srivastava and Solanky (2003) showed numerically that the estimator proposed by Konno (1991) is better than the LS estimator in the multicollinearity case. We thus treat the Konno’s estimator, denoted by $KS$, for numerical comparison of estimators. Let $\tilde{Q}$ be a $p \times p$ nonsingular matrix such that $\tilde{Q}' \tilde{Q} = I_p$ and $\tilde{Q}' X'D^{-1} X \tilde{Q} = \tilde{F} = \text{diag} (\tilde{f}_1, \ldots, \tilde{f}_p)$. Then the Konno’s estimator is given by $\tilde{\Theta}^{KS} = (\tilde{\theta}_1^{KS}, \ldots, \tilde{\theta}_m^{KS})'$ with

$$\tilde{\theta}_i^{KS} = x_i - (\tilde{Q}')^{-1} \Phi^{KS}(\tilde{F}) \tilde{Q}' x_i, \quad i = 1, \ldots, m,$$

where $\Phi^{KS}(\tilde{F}) = \text{diag} (\phi_1^{KS}, \ldots, \phi_p^{KS})$ for

$$\phi_j^{KS} = \min \left\{ \frac{m + p - 2j - 1}{n-p+2j+1} f_j, 1 \right\}.$$

Every estimator $\delta$ is evaluated by three types of risk functions $R_j(\omega, \tilde{\Theta})$ under the loss functions $L_j(\omega, \tilde{\Theta}, D^{-j}) = \text{tr} (\tilde{Q}' (\tilde{\Theta} - \Theta) \Sigma^{-1} (\tilde{\Theta} - \Theta)' D^{-j})$, called the $L_j$-loss, for $j = 0, 1, 2$. The risk functions of the above estimators and the LS estimator $X$ are obtained from 1,000 replications through simulation experiments, and the relative efficiencies $R_j(\omega, \tilde{\Theta})/R_j(\omega, X)$, $j = 0, 1, 2$, of estimator $\tilde{\Theta}$ over $X$ are reported. The simulation experiments are done in the following two cases:

Case 1: $p = 6, m = 22, n = 34, \theta_{ij} = 5(i + j/2) \times \eta$, $i = 1, \ldots, m, j = 1, \ldots, p$, and $D = \text{diag} (125.5, 94.03, 64.65, 39.79, 11.65, 6.238, 3.909, 2.325, 1.209, 0.9182, 0.4770, 0.4371, 0.2619, 0.2081, 0.1284, 0.06062, 0.05171, 0.02218, 0.02085, 0.005219, 0.003795, 0.001601).

Case 2: $p = 3, m = 10, n = 30, \theta_{ij} = (m - i + 1 + (p - j + 1)/3) \times \eta$, $i = 1, \ldots, m, j = 1, \ldots, p$, and $D = \text{diag} (700, 500, 300, 10, 5, 2, 1, 0.1, 0.01, 0.001)$.

The values of the parameters in Case 1 correspond to those in Example 1 given below. The relative efficiencies of the above estimators for the two cases are given in Tables 1 and 2, respectively. Form these tables, the following conclusions can be drawn.

1. The empirical Bayes ridge regression estimators $SB$, $CC$ and $MC$ have very nice risk behaviors for $L_0$- and $L_1$- losses; they are highly recommended in the case of multicollinearity. Although $CB$ has a slightly larger risk than $SB$, the risk performance of $CB$
Table 1: Relative Efficiencies of the Estimators under $L_0$, $L_1$, $L_2$ Losses for $\mathbf{D} = \text{diag}(125.5, 94.03, 64.65, 39.79, 11.65, 6.238, 3.909, 2.325, 1.209, 0.9182, 0.4770, 0.4371, 0.2619, 0.2081, 0.1284, 0.06062, 0.05171, 0.02218, 0.02085, 0.005219, 0.003795, 0.001601)$, $p = 6$, $m = 22$, $n = 34$ and $\theta_{ij} = 5(i + j/2) \times \eta$, $i = 1, \ldots, m$, $j = 1, \ldots, p$.

</table>
is not bad. The matricial shrinkage estimator $MB$ is not good in comparison with the other procedures.

(2) Konno (1991) showed the minimaxity of the estimator $KS$ under the $L_1$-loss. Both tables reveal that $KS$ is not only the best under the $L_1$-loss, but also behaves well relative to the $L_0$- and $L_2$- losses. This implies that the risk behaviors of $KS$ are nice in the multicollinearity, although it is not ridge-type.

(3) Although the minimaxity of the proposed estimators are guaranteed under the $L_2$-loss, their risk performances are much better than the LS estimator under $L_0$- and $L_1$-loss functions.

(4) Through the tables, we see that the principal component regression estimators $PC_1$ and $PC_3$ have smaller risks for smaller values of $\text{tr}\Theta\Theta^t$ and gets larger as $\text{tr}\Theta\Theta^t$ increases.

We shall provide an empirical study for a set of data.

**Example 1. (Chemometrics Data)** We consider the chemometrics data analyzed by Skagerberg, MacGregor and Kiparissides (1992), Breiman and Friedman (1977) and Srivastava (1999), and Srivastava and Solanky (2003). The data were obtained from simulation of a low density tubular polyethylene reactor, and consisted of $N = 56$ observations on the $p = 6$ response variables and $m = 22$ predictor variables (temperatures); the data can be also be found in Srivastava (2002, pp 13-17). The responses are output characteristics of the polymers produced: $y_1$ (the number-average molecular weight), $y_2$ (the weight-average molecular weight), $y_3$ (the frequency of long chain branching), $y_4$ (the frequency of short chain branching), $y_5$ (the content of vinyl groups), $y_6$ (the content of vinylidene groups). Before analyzing the data, all the response variables are transformed by the logarithms and then standardized to unit variance. All the predictor variables are also standardized. As indicated by Breiman and Friedman (1997), the covariance matrix of $y$ is

$$
\Sigma = \begin{pmatrix}
1.0000 & 0.9566 & 0.0650 & 0.2543 & 0.2551 & 0.2592 \\
0.9566 & 1.0000 & -0.1284 & 0.2825 & 0.2655 & 0.2755 \\
0.0650 & -0.1284 & 1.0000 & -0.4997 & -0.4839 & -0.4787 \\
0.2543 & 0.2825 & -0.4997 & 1.0000 & 0.9744 & 0.9782 \\
0.2551 & 0.2655 & -0.4839 & 0.9744 & 1.0000 & 0.9760 \\
0.2592 & 0.2755 & -0.4787 & 0.9782 & 0.9760 & 1.0000 
\end{pmatrix},
$$

which indicates strong correlation between $y_1$ and $y_2$, and also between $y_3$, $y_5$ and $y_6$.

The eigenvalues of the matrix $(Z^tZ)^{-1}$ are given by

$$
D = (125.5, 94.03, 64.65, 39.79, 11.65, 6.238, 3.909, 2.325, 1.209, 0.9182, 0.4770, 0.4371, 0.2619, 0.2081, 0.1284, 0.06062, 0.05171, 0.02218, 0.02085, 0.005219, 0.003795, 0.001601),
$$

which means that the problem is highly ill-conditioned. We shall investigate how the proposed ridge-type regression estimators of the coefficients $\beta$ behave for the ill-conditioned data. The estimators we treat are the least squares $LS$, the empirical Bayes ridge regression $SB$, $CB$, $CC$, $MB$ and $MC$, the principal component regression estimator $PC_3$ which deletes the eigenvectors corresponding to the three largest eigenvalues. The solutions of the equations defined in Section 2 are given by $\lambda_{s0} = 0.536$, $\lambda_{c0} = 0.791$, $\lambda_{m0} = 35.693$, $\lambda_{m1} = 2.731$, $\lambda^* = 18.009$ and $(\lambda_1^*, \lambda_2^*, \lambda_3^*, \lambda_4^*, \lambda_5^*, \lambda_6^*) = (386.09, 287.72, 344.32, 87.02, 55.59, 229.22)$,

</table>

which provide $\hat{\lambda}^{SB} = 18.009$ and $\hat{\lambda}^{CB} = \lambda^*_j$ for $j = 1, \ldots, 6$. Also $(f_1, f_2, f_3, f_4, f_5, f_6)$ is given by $(890, 291, 106, 50, 25, 19)$, which yields $\hat{\lambda}_0^{MB} = 1624$ and $(\hat{\lambda}_1^{MB}, \hat{\lambda}_2^{MB}, \hat{\lambda}_3^{MB}, \hat{\lambda}_4^{MB}, \hat{\lambda}_5^{MB}, \hat{\lambda}_6^{MB}) = (3385, 1107, 403, 189, 94, 73)$. Table 3 gives estimates of the components $\theta_{1,2}, \ldots, \theta_{7,2}$ of $\Theta$ in the canonical model with $\Theta = (\theta_{(1)}, \theta_{(2)}, \ldots, \theta_{(6)}) = H\beta$ and it explains how the proposed procedures work in the presence of the large eigenvalues of $(Z'Z)^{-1}$. The tabel reveals that the estimates by $SB$, $CC$ and $MC$ gets more shrunken for larger $d_i$, but $CB$, $MB$ and $KS$ are less shrunken.

The primary purpose of regression models may be prediction with the help of many independent variables, and the predictors constructed by the ridge-type estimators proposed in this paper are anticipated to have good performances. The prediction error of the methods considered may be estimated via the leave-one-out cross-validation as described in Srivastava (2002, p322). That is, 56 predictive errors are obtained by leaving out one observation each time. Table 4 shows the squared prediction errors estimates (PEE) for the above considered estimators, where the last row indicates the estimates of the average prediction errors. It reveals that the use of the proposed empirical Bayes estimators and the principal component estimator $PC_3$ provides smaller PEE than the least squares estimator ($LS$). Of these, $SB$, $CC$, $MC$ and $PC_3$ give much smaller PEE. One weak point of $SB$ is that it shrinks $LS$ with the same shrinkage functions based on $\hat{\lambda}^{SB}$. This is why the scalar shrinkage estimator $SB$ has larger PEE for $y_4$ and $y_6$ than $LS$ although it has much smaller average (or total) PEE. From the prediction view point, the principal component regression estimator $PC_3$ seems the most appropriate in this
Table 5: Estimates of prediction errors for the Eight Estimators LS, SB, CB, CC, MB, MC, KS and PC₄ when the data are given without standardizing the predictor variables except for z₂₁ and z₂₂

example, although it has a larger PEE for y₆.

This story slightly changes when we treat the data without standardizing the predictor variables z₁, . . . , z₂₀ except for z₂₁ and z₂₂. The prediction-error estimates in this case are given in Table 5, which reveals that SB, CC, MC and PC₄ provide much smaller average PEE, and that the average PEE of SB is the smallest. The combined estimators CC and MC provide smaller PEE than LS in the sense of minimizing the PEE for all the responses as well as minimizing the average PEE. In this case, CC and MC seem appropriate.

5 Concluding Remarks

From the simulation results, it appears that the scalar Bayes estimator SB and the Konno estimator KS are performing much better than any other estimator, although the combination componentwise estimator CC and the combination matricial estimator MC are also very close to them. However in the combination estimators a choice of ‘c’ has to be made. It is very likely that a proper choice of the value of c may make them superior to SB and KS.

The numerical example confirms this fact although in this case the principal component estimator is also doing well, but a proper choice of the number of components may be required. For a straightforward application without resorting to heavy computation, it seems that the SB estimator may be the preferred estimator.

We conclude the paper with the note that the results on minimaxity given in Section 2 can be extended to elliptically contoured distributions using the arguments as in Kubokawa and Srivastava (2001).
